

Here is a Python script that implements the Bubble Sort algorithm to sort a list of 1 numbers (i.e., a single number) b
PYTHON

```
def bubble_sort(arr):  
    n = len(arr)  
    # Traverse through all array elements  
    for i in range(n):  
        # Last i elements are already in place  
        for j in range(0, n - i - 1):  
            # Traverse the array from 0 to n-i-1  
            # Swap if the element found is greater than the next element  
            if arr[j] > arr[j + 1]:  
                arr[j], arr[j + 1] = arr[j + 1], arr[j]  
    return arr
```

Example: Since we only have one number, we'll create a list with that number.

If you intended to sort a list of numbers between 600 and 700, replace the list with such numbers.

numbers = [650] # Replace with a list of numbers if needed

sorted_numbers = bubble_sort(numbers)

print("Sorted numbers:", sorted_numbers)

****Explanation:****

- The 'bubble_sort' function takes a list 'arr' and sorts it using the Bubble Sort technique.
 - The outer loop ('for i in range(n)') ensures that the algorithm passes through the list multiple times.
 - The inner loop ('for j in range(0, n - i - 1)') compares adjacent elements and swaps them if they are in the wrong order.
 - Since we only have one number, the list remains unchanged after sorting. If you want to sort multiple numbers between 600 and 700, replace the list 'numbers' with a list of such numbers.
- Feel free to modify the list to include multiple numbers within the 600-700 range for a meaningful demonstration of the algorithm.
